

**APPENDIX DR- A**  
**ANALYTICAL METHODS AND  $^{40}\text{Ar}/^{39}\text{Ar}$  DATING RESULTS**

**A. Analytical Methods**

Twenty volcanic samples from the Valle Central and Orotina debris fan were dated by the  $^{40}\text{Ar}/^{39}\text{Ar}$  technique in the Geochronology Laboratory at Lehigh University. The samples were collected from recent quarry and roadcut exposures. Visibly altered material was rejected wherever possible; however, due to the high porosity of many of the sampled units and the intense tropical weathering pervasive in the field area, some of the samples show evidence of slight to moderate low-temperature alteration.

The alteration and low potassium content of these young andesitic and basaltic rocks dictated the choice of minerals available for dating. Plagioclase and biotite, occurring primarily as phenocrysts and microphenocrysts, were separated from some of the volcanic rocks using standard heavy-liquid and magnetic techniques. The groundmass of several fresh, well-crystallized volcanic rocks was also dated. Olivine and pyroxene phenocrysts were removed from these rocks prior to irradiation in order to reduce excess  $^{40}\text{Ar}$  contamination. All of the samples were hand-picked to >99% purity prior to irradiation.

The purified separates were packaged in Sn foil and sealed in evacuated quartz vials. Packets containing monitor mineral GA1550 biotite (97.9 Ma; McDougall and Roksandic, 1974) were spaced evenly throughout the tubes to record the vertical variation in neutron flux within the irradiation container.  $\text{CaF}_2$  and  $\text{K}_2\text{SO}_4$  were also included in the irradiation packages to monitor neutron-induced interferences from Ca and K, respectively. The samples were irradiated in three separate batches in the L67 position of the Ford Reactor at the University of Michigan, each irradiation lasting 2 hours.

Argon was extracted from the samples by stepwise heating in a double-vacuum resistance furnace, and purified using a cold finger cooled to liquid nitrogen temperature and SAES St101 getters operated at room temperature and 400°C. The analyses were performed with a VG3600 noble gas mass spectrometer equipped with an electron multiplier operated in the analog mode. The mass spectrometer sensitivity was  $\sim 6 \times 10^{-17}$  moles/mV  $^{40}\text{Ar}$ . Both the extraction line and mass spectrometer were operated under computer control using LabSpec, a custom LabVIEW program developed by Bruce Idleman at Lehigh University. Extraction line blanks were typically  $\sim 3 \times 10^{-15}$  moles  $^{40}\text{Ar}$  at 1350°C and  $< 1 \times 10^{-15}$  moles  $^{40}\text{Ar}$  at temperatures below 1000°C, and were approximately atmospheric in composition. The isotopic data were corrected for extraction line blank, mass spectrometer background, mass discrimination, radioactive decay of  $^{37}\text{Ar}$  and  $^{39}\text{Ar}$ , neutron-induced interferences, and atmospheric contamination prior to calculation of the ages. The interference corrections varied slightly between the three irradiations. Their average values were:  $(^{36}\text{Ar}/^{37}\text{Ar})_{\text{Ca}} = 0.000227$ ,  $(^{39}\text{Ar}/^{37}\text{Ar})_{\text{Ca}} = 0.000790$ , and  $(^{40}\text{Ar}/^{39}\text{Ar})_{\text{K}} = 0.0252$ . Mass discrimination averaged 0.75%/AMU over

the course of the experiments (average measured atmospheric  $^{40}\text{Ar}/^{36}\text{Ar} = 286.9 \pm 0.75\%$ ).

The results of the dating experiments are summarized in Table 1. A complete tabulation of the analytical data is presented in Appendix 1. The ages were calculated using the decay constants and isotopic abundances of Steiger and Jager (1977). Uncertainties associated with the ages reported in Table 1 and this appendix are quoted at the  $1\sigma$  level and incorporate a 1% uncertainty in the J factor. The uncertainties reported for individual step ages in reported in the data tables in the appendix represent only the analytical component of the total uncertainty.

Plateau ages reported in Table 1 and in this appendix are the inverse-error weighted mean ages of contiguous steps that comprise 50% or more of the gas released from a sample and define individual ages statistically indistinguishable from the weighted mean at the  $2\sigma$  analytical error level. For samples that do not define a statistically significant plateau but yielded several contiguous steps with nearly concordant ages, we report an inverse-error weighted mean age (i.e., an incremental or “near-plateau” age) for these steps. These ages are enclosed in parentheses where they are reported in the appendix. Isochron ages were determined by regressing blank-corrected data plotted on  $^{36}\text{Ar}/^{40}\text{Ar}$  vs.  $^{39}\text{Ar}/^{40}\text{Ar}$  isotope correlation diagrams using the method of York (1969). In general, we report the isochron age as the preferred age for samples that yielded acceptable isochrons (MSWD < 2.5); otherwise plateau or integrated ages are reported.

## B. Summary of Dating Results

Sample Number	Field ID Number	Rock Type (Material Dated)	Location	Lat.	Long.	Plateau Age <sup>†</sup>	Isochron Age <sup>†</sup>	MSWD <sup>#</sup>
<b>Formación Orotina (Qv2)</b>

---

<sup>1</sup> Corrected for mass spectrometer background, extraction line blank, mass discrimination, and radioactive decay of <sup>37</sup>Ar and <sup>39</sup>Ar.

<sup>2</sup> Corrected for (1) above plus atmospheric argon and neutron-induced interferences.

<sup>3</sup> Ages calculated using the decay constants of Steiger and Jager (1977).

<sup>4</sup> Analytical uncertainties quoted at the 1 $\sigma$  level. Uncertainties for total-gas ages include a 1% J-factor contribution.
